7. Hierarchies & Trees
Visualizing topological relations

Vorlesung „Informationsvisualisierung“
Prof. Dr. Andreas Butz, WS 2012/13
Konzept und Basis für Folien: Thorsten Büring
Outline

• Hierarchical data and tree representations
• 2D Node-link diagrams
  – Hyperbolic Tree Browser
  – SpaceTree
  – Cheops
  – Degree of interest tree
  – 3D Node-link diagrams
• Enclosure
  – Treemap
  – Ordererd Treemaps
  – Various examples
  – Voronoi treemap
  – 3D Treemaps
• Circular visualizations
• Space-filling node-link diagram
Hierarchical Data

• Card et al. 1999: data repository in which data cases are related to subcases

• Many data collections have an inherent hierarchical organization
  – Organizational Charts
  – Websites (approximately hierarchical)
  – File system
  – Family tree
  – OO programming

• Hierarchies are usually represented as tree visual structures

• Trees tend to be easier to lay out and interpret than networks (e.g. no cycles)

• But: as shown in the example, networks may in some cases be visualized as a tree

Yee et al. 2001 see previous lecture...
Tree Representations

- Two kinds of representations
- Node-link diagram (see previous lecture): represent connections as edges between vertices (data cases)
- Enclosure: space-filling approaches by visuallynesting the hierarchy

http://www.icann.org
Node-Link Diagram

• Most conventional layout
  – Tree-depth is mapped to an ordinal Y-axis
  – X-axis is nominal – mainly used to separate siblings

• Can also be turned around

• Circular layout – root in the center with levels growing outward
Node-Link Diagram

• Unlike space-filling methods, node-link diagrams provide an effective overview of the topology of a tree

• Problems:
  • Large trees require an extreme aspect ratio
    – Example: branching factor of 2
    – Tree gets wider approximately proportionally $2^n$ (n= level) ...
    – ... and taller only proportionally to n
    – Large trees become to resemble a straight line
  • Trees usually contain considerable empty space (about 50%)
  • InfoVis approaches to address these problems
    – Interaction
    – Distortion

Hyperbolic Tree Browser

• Lamping et al. 1995
• Comparable to fisheye distortion
  – Nodes in the center are displayed at higher granularity
  – Neighboring nodes are displayed in diminishing size
• Maximum number of nodes displayed in a 600 x 600 pixel window
  – Standard 2D hierarchy browser: typically 100 nodes with 3 characters text labels
  – Hyperbolic browser: can display 1000 nodes with 50 nearest the focus can show from 3 to dozens of characters text labels
• Approach exploits hyperbolic geometry
  – Lay out hierarchy on hyperbolic plane and map plane onto a circular display region
  – Property of hyperbolic plane: circumference of a circle grows exponentially with its radius
  – Hierarchies tend to expand exponentially with depth
  – Elegant match!
Hyperbolic Tree Browser

- Navigation: users select nodes to become the new center node (animated transitions)
- Potential problem with orientation:
  - nodes rotate during pure translation, e.g. node “Lowe” moves from top right to bottom right
  - Not suitable to present data such as organizational charts
- Small-scale user test (4 subjects, within-subjects design, IV: type of browser, DV: number of actions, time, preference)
  - No significant performance advantage over a 2D hierarchy browser with horizontal tree layout
  - Participants preferred the hyperbolic tree browser - provided “weaker sense of directionality of links”, but helped to “get(ting) a sense of the overall tree structure”

Lamping et al. 1995
SpaceTree

• Plaisant et al. 2002
• Mechanisms to facilitate large tree exploration / navigation
  – Dynamic rescaling of branches to fit the screen
    • De-composed animated transitions
  – Optimized camera movement
  – Preview icons summarizing branches collapsed (see top-down order)
    • Shading of triangle is proportional to the total number of nodes in the subtree
    • Height of triangle represents depth of subtree
    • Base of triangle proportional to average width (number of items / depth)
  – Search and filter functionality
• Video
SpaceTree

- Experiment comparing 3 tree-browsing interfaces
  - Microsoft Explorer
  - Hyperbolic tree browser
  - SpaceTree

- Counterbalanced repeated-measures within-subject design

- 18 participants

- Tree with 7000 nodes

- Three task types
  - Node searches
  - Search of previously visited nodes
  - Answering topology questions

- Results
  - Hardly significant performance differences between the interfaces
  - Users found MS Explorer significantly less attractive than the other two interfaces
Cheops

• Beaudoin et al. 1996
• Exploring and navigating large graphs
  – Maintain context
  – Provide easy access to details
• Cheops provides effective compression by reusing visual components based on interaction
• Compress the hierarchy by tessellation of triangles
  – In the example triangle 5 could represent either node E or node F
  – If triangle 2 is selected, triangle 5 will become node E …
  – Overlapping triangles to indicate larger hierarchy
  – The example shows an expansion by adding 5 children per parent
• But: users cannot compare topologically remote parts of a structure
Cheops

- Another example
- Three triangles in the last level represent more than one logical node
- If a parent node (e.g. B) is selected the visual components become unambiguous
- Selection of a node implies previous selection of all its parent nodes
- Nodes are represented as paths of visual objects going down from the root – not isolated triangles
Cheops

- Visual cues and terminology to aid interpretation of the compressed visualization
- Selection: deployment of branches
- Pre-selection: direct access to any node
Degree of Interest Tree

- Nation et al. 2002
- For interactive display of hierarchies within a web browser
- Based on Furnas Degree-of-interest function
  - Each node is assigned a value
  - Degree-of-interest value is determined by a function of a node’s distance from the root of the tree and its distance from the focus of interest
  - Topic of later lecture on focus+context presentation techniques!

- DOI Tree
  - Upon selection: focused node is allocated most space
  - Remaining space is allocated to nodes based on their DOI values
  - Nodes with more space present more details
Degree of Interest Tree

- Animated transitions
- Reset the tree layout by clicking on the root node
- Tree does not fit the screen in the Y-dimension
  - Prune parts of the tree below a given DOI threshold
  - Pruned branch is represented by a symbol
- Tree does not fit the screen in the X-dimension – visually compress peripheral nodes

3D Approaches

• Why not use an additional dimension to visualize nodes that would otherwise be pruned / collapsed?
  – Cone Tree
  – H3Viewer

• HCI research produced mixed results about the usability of 3D interfaces

• Ongoing research question: do 2D interfaces better exploit the abilities of the human perceptual system?
  – Utilize spatial memory?
  – Controlling 3D navigation with 2D input devices?

• 3D node-link approaches have been mainly researched in the 90s
Cone Tree

- Robertson et al. 1991
- Use depth to make more effective use of screen space
- Hierarchies laid out uniformly in three dimensions
- When a node is selected by a user the tree rotates to bring the node to the front
- Animation to make the users comprehend the rotation
- Problem: still clutter and occlusion
Cone Tree

- Usability evaluation by Cockburn & McKenzie 2000
- Compare Cone Tree to conventional explorer-like 2D tree browser
- User test with 12 participants
- Independent variables: depth, density of tree, interface type
- Dependent variables: task-completion time, user preference
- Results
  - Users were slower in locating data using the Cone Tree
  - Performance deteriorated rapidly with a growing branching factor
  - But: participants clearly preferred the Cone Tree…
H3Viewer

• Munzner 1997
• H3Viewer supports interactive exploration of large graphs (> 100,000 edges)
• Graph is presented in 3D hyperbolic space
• Child nodes are distributed on the surface of a hemisphere
• Users can drag and rotate graph
• Java 3D implementation and gallery: http://www.caida.org/tools/visualization/walrus/
Treemap

• Johnson & Shneiderman 1992
• Basic idea
  – Map hierarchical data to rectangular 2D display area by recursively partitioning the screen into rectangular boxes representing nodes
  – Utilize 100% of the screen
• Less good for analyzing the topology of a tree
• Advantages
  – Very effective when focusing on leaf nodes and their attributes
  – More suitable for additional encoding via color, size, shape
  – Present large hierarchies on a single screen

Image taken from Spence 2007
Treemap

• Nested versus non-nested Treemaps
Treemap

• Shneiderman 1992
• Slice and dice algorithm
  – Use parallel lines to divide a rectangle representing an item into smaller rectangles representing the item’s children
  – Each child is allocated a size proportional to some property (additional encoding by color)
  – At each level of the hierarchy switch the orientation of the lines (vertical vs. horizontal)
• Example application: file browser
  – Size: file size, color: file type
  – Users can easily identify large file
  – Detect duplicate directories
  – …

Treemap: Discussion

- Problems with this layout?
- Creates layouts that contain many rectangles with a high aspect ratio
- Thin rectangles are hard to see, select, label and compare in size
- Which of the blue rectangles is bigger?
Treemap

- Several algorithms to create more useful tree-maps by reducing the overall aspect ratios of the map rectangles
- Cluster algorithm (Wattenberg1999):
  - employ both vertical and horizontal partitions at each level of the hierarchy
- Squarified algorithm (Bruls et al. 2000)
  - Sorts and adds the input rectangles ordered by size
- Problem of both algorithms
  - Changes in the data set can cause dramatic layout changes (hard to track items given dynamic data)
  - Given ordering of items is not preserved (as indicated by shading)
Ordered Treemap

- Seek compromise between smooth updates and low aspect ratios
- Items are given as a list ordered by index and have varied areas
- Items that are next to each other in the given order should be approximately adjacent in the tree-map
- Shneiderman & Wattenberg 2001
- Pivot-by-size & Pivot-by-middle
  - Partition area into 4 regions
  - Pick pivot element Rp
    - Size: largest item
    - Middle: middle item
  - Depending on the aspect ratio of R, place Rp in horizontal oder vertical middle
  - R1: items earlier in the list than pivot (sublist L1)
  - R2: items in list before R3 such that their overall size makes Rp have aspect ratio closest to 1 (sublists L2, and L3)
  - Apply steps recursively for areas R1, R2, and R3
Ordered Treemap

• Strip treemap - Bederson & Shneiderman 2002
• Modification of squarified algorithm
• Produces better readability than basic ordered treemap algorithms and comparable aspect ratios (only slightly worse than unordered squarified algorithm)
• Rectangle is filled stepwise with strips
• Strip is filled stepwise with rectangles as long as the average aspect ratio of the strip decreases or stays the same
• Otherwise a new strip is added
Ordered Treemap

- Test with several generated data sets
- Table shows results for three levels of hierarchy and eight items at each level
- 100 trials of 100 steps each
- Comparing the algorithms by average aspect ratio and average layout distance change (how much do rectangles move as data is updated) and readability (how easy it is to visually scan a layout to find a particular item)
- Tradeoff between low aspect ratios and smooth updates!

Ordered Treemap

- Applying the algorithms to real-world data - confirmed prior test results
- Set of 535 publicly traded companies, market capitalization as the size attribute
- Gray scale indicates ordering within each industry group that is the last level of hierarchy in this data set

Slice-and-dice layout
Pivot-by-middle layout
Pivot-by-size layout

  • http://www.cs.umd.edu/hcil/treemap-history/java_algorithms/LayoutApplet.html

• History of treemaps
  • http://www.cs.umd.edu/hcil/treemap-history/

• Java 1.1 library for five Tree-map algorithms:
  • http://www.cs.umd.edu/hcil/treemap-history/Treemaps-Java-Algorithms.zip
Ordered Treemap

- Bederson et al. 2002
- User study of layout readability
- Compared the squarified, pivot-based, and strip treemap algorithms
- 20 Participants had to identify a specific rectangle by clicking on the rectangle with the requested numerical ID
- Repeated-measures design
- Independent variable: treemap algorithm
- Dependent variable: time, subjective user rating
- Time: significant difference between squarified algorithm and the other two
- Preference: significant difference between all three algorithms
- Validates readability metric used
Map of the Market

- Wattenberg 1999
- Cluster treemap to reduce overall aspect ratios
- 500 stocks updated every 15 minutes
- Each rectangle represents a company
  - Size: company's market capitalization
  - Color: price performance
- Double-ended multiple hue color coding
  - Green: stock price is up
  - Red: stock price is down
  - Black: neutral, no change
- Detailed information on-demand
- Demo if time..

Peet's Coffee: Coffee Selector

2012 White House Budget Proposal

US Presidential Elections 2012
US Presidential Elections 2012
TennisViewer

- Jin & Banks 1997
- Visualize a tennis match using a treemap
- Match tree
  - Root node – the tennis match
  - Match node subdivides horizontally into sets
  - A set subdivides vertically into games
  - A game subdivides horizontally into points
- Color mapping of rectangles show node ownership (who won what?)
- Translucent child rectangles are layered over parent rectangles
TennisViewer

- Magic Lens to explore ball traces
- Example: the return of a service goes out of bounds
FundExplorer

• Csallner et al. 2003
• To support the diversification of mutual fund portfolios, i.e. how to find funds with little overlap in their investments
• Also show stocks with zero investment
Voronoi Treemap

• Balzer et al. 2005
• Treemap consisting of arbitrary polygons instead of rectangles
  – Aspect ratio of polygons converges to 1
  – Polygons are distinguishable due to the irregular shapes
  – Avoid that edges of different objects run into each other
Cushion Treemap

- Wijk & van de Wetering 1999
- Treemaps usually fall short to visualize the structure of the tree
- Worst case: a balanced tree, where each parent has the same number of children and each leaf the same size
- Outcome: regular grid
- Nested treemap may reduce this problem, but:
  - Margins require screen space
  - Deeply nested trees are difficult to read
- Idea: add shading and texture to help convey the structure of the tree
Some really useful Cushion Treemaps

- **SequoiaView** [http://w3.win.tue.nl/nl/onderzoek/onderzoek_informatica/visualization/sequoiaview/](http://w3.win.tue.nl/nl/onderzoek/onderzoek_informatica/visualization/sequoiaview/)
- **GrandPerspective** [http://grandperspectiv.sourceforge.net](http://grandperspectiv.sourceforge.net)
- Visualize the contents of your hard drive
StepTree

• Bladh et al. 2004
• Convey tree structure via third dimension
• http://www.sm.luth.se/csee/csn/visualization/filesysvis.php
Sunburst

- Stasko & Zhang 2000
- Full circular visualization to give each element more space
- Navigating the tree should not lead to significant node position changes (e.g. hyperbolic browser)
- Three animated approaches to provide a focus area while maintaining context
  - Angular detail method
  - Detail outside method
  - Detail inside method
- Comparative evaluation of sunburst vs. treemap did not show significant differences in task completion times, but participants strongly preferred sunburst (Stasko et al. 2000)
- Radial visualizations may better depict the structure of the tree, but are not as space-efficient as treemaps (Movie)
Focus+Context Display and Navigation Techniques for Enhancing Radial, Space-Filling Hierarchy Visualizations

John Stasko and Eugene Zhang

College of Computing and GVU Center
Georgia Institute of Technology
Pebbles - Circular Treemaps

• Kay Wetzel (2003)
• Do not fill space completely,
• but...
  – Aspect ratio stays the same for all elements – easy comparison of sizes
  – Good visibility of nesting (though at the cost of unused space)
  – Rather beautiful layout!

Visualization of a file system with color mapping for creation data
Enclosure + Connection

- EncCON: Nguyen & Huang 2005
- Connection (node-link)
  - Gives immediate perception of data relationships and the tree structure
  - Not efficient regarding display space utilization: most pixels are wasted as background
- Enclosure (e.g. treemaps)
  - Space-filling approach allows the display large trees on a single glance
  - Focus on the leaf nodes but hardly conveys the tree structure
- Idea: combine enclosure and connection approach
- Child nodes are not embedded but placed around parent nodes using a circular, space-filling division method
- Focus+context navigation
